

Saving Native Hawaiian Forest Birds Is In All Of Our Hands

What is a forest bird?

Most forest birds are smaller than chickens, seabirds or geese, usually just a few inches from the tips of the tail to the bill. Most nest, rest and feed in shrubs and trees. Many are brightly colored and have unique songs.

What makes them special?

The ancestors of today's Hawaiian forest birds arrived many thousands of years ago by accident, maybe caught up in storms while flying. To survive, they adapted what they ate and over time, even their beaks changed to take advantage of different foods. Without many predators, different species developed, sometimes living in just one area of one island. All of the birds celebrated in the **Makahiki o Nā Manu Nahele** are endemic to the Hawaiian Islands, found here and nowhere else in the world. They are irreplaceable.

What's happening to them, why are they so rare?

Hawaiian forest birds once lived all the way down to the sea. Mosquitoes spread diseases between birds, so when they were accidentally brought to Hawai'i, the birds could only survive where the mosquitoes could not reach them, high in the mountains. Cats, mongooses and rats eat eggs and kill adult birds. Deer, goats, sheep and pigs destroy forest bird habitats. Hawai'i once had over 84 different species of forest birds. Today only 26 survive, and several may go extinct in just a few years.

How can you help?

- Keep cats indoors!
- Make sure mosquitoes cannot breed in standing water around your home or school.
- Teach each other about our native forest birds.
- Create and fly a flock of origami Hawaiian forest birds to help raise awareness!

Why do forest birds have different looks and calls?

Forest birds can see colors so bright feathers and patterns help them recognize other birds that may be either friends, mates or competitors. Calls and songs also communicate these things in the forest. Different bill shapes allow each species to eat something different from others.

What do they do for us?

Honeycreepers that specialize in eating nectar pollinate native flowering trees and shrubs. Seed-eating forest birds help spread seeds. Insect-eating birds control insects and recycle nutrients. Most of them use lichens and mosses for building nests. Their feeding and nesting work helps forests be more productive and healthy, making more oxygen and storing more fresh water – things all creatures need, including people! Hawaiian forest birds are important in Hawaiian *mo'olelo*, *mele*, *oli*, *hula*. They have long been considered *kinolau*, and some *'amaukua*.

Students across Hawai‘i are asked to create one origami of a native Hawaiian forest bird from their island for the **Makahiki o Nā Manu Nahele**, to inspire each community to learn about and care for our precious forest gems!

How should my Laysan Finch origami look?

Laysan Finches are about five inches long, with a strong, short cone-shaped beak. Beak and legs are black. Males are bright yellow on their heads and chest, with patches on their wings, and gray-black underneath. Females are brownish mixed with some yellow on the chest and belly.

Laysan Finch (*Telepiza cantans*)

Laysan Finches are omnivores, which means they eat a variety of things. Their strong beak can crack seeds, and they eat insects, roots, leaves, flowers, even other bird's eggs. They sing a variety of songs. Laysan Island has few trees and short shrubs, so these finches are unusual because they nest on the ground. Introduced grasshoppers and plants impact the native plants and ultimately, Laysan Finches. If introduced rats and mice stow away on a boat, that will pose a problem, because they eat eggs and as well as the plants. Laysan Island is not very tall - only about three feet, and their habitat is only about 450 acres. Because of climate change, oceanographers expect sea level to rise enough in the next 50 years to make most of Laysan go underwater, especially during big storms. For all these reasons, they are considered critically endangered, and they are endemic, found nowhere else in the world.
