## Executive Summary

This report summarizes work performed by Kaheawa Wind Power, LLC (KWP I), owner of the Kaheawa Wind Power I Project (Project), during the State of Hawai'i fiscal year (FY) 2023 (July 1, 2022 – June 30, 2023) under the terms of the approved Habitat Conservation Plan (HCP). The HCP was approved in January 2006 and describes KWP I's compliance obligations under Project's state Incidental Take License (ITL-08) and federal Incidental Take Permit (TE118901-1). Species covered under the HCP include four federally and state-listed threatened and endangered species (Covered Species). The 20-turbine Project was constructed in 2005 and 2006 and has been operating since June 22, 2006.

Wildlife fatality monitoring in FY 2023 continued within search plots limited to cleared areas within 70-meters of each Wind Turbine Generator (WTG). Canine-handler teams searched each of the fatality monitoring search plots once per week year-round. Bias correction trials were conducted quarterly at the Project to measure the probability that a carcass would persist until the next search (carcass persistence) and the probability that an available carcass would be found (searcher efficiency) by a canine search team. In FY 2023, mean probabilities of a carcass persisting until the next search were 0.92 (bat surrogates), 1.00 (nēnē surrogates), and 0.99 (seabird surrogates); searcher efficiency was 0.95 for surrogates of the 'ōpe'ape'a (the Hawaiian hoary bat) and 1.00 for surrogates of each of the other two species groups.

Four fatalities of Covered Species were detected in FY 2023. One 'ōpe'ape'a was detected in March 2023. Three nēnē fatalities were detected (two incidental finds detected during a scheduled search but outside of the defined search area) in January 2023 while one fatality was detected during a scheduled search and within the defined search plot in April 2023. Since the commencement of operations, the Project's total observed direct take of Covered Species has been 13 'ōpe'ape'a, 34 nēnē, and 8 'ua'u. The fatality estimates using the Evidence of Absence estimator at the upper 80 percent credibility level are 28 'ōpe'ape'a, 52 nēnē, and 18 'ua'u. Rounded up indirect take estimates for the Covered Species are four 'ōpe'ape'a, two nēnē, and five 'ua'u. Combining these values, there is an approximately 80 percent chance that cumulative take of Covered Species at the Project since the beginning of operations through FY 2023 was less than or equal to 32 'ōpe'ape'a, 54 nēnē, and 23 'ua'u.

The bat acoustic monitoring program captured bat activity across the Project at five detector locations throughout FY 2023. Between July 2022 and June 2023, the 'ōpe'ape'a were detected on 214 nights out of 1,778 detector-nights sampled (12.0 percent). Detection rates were highest between the months of August and October during the lactation and post-lactation reproductive periods, with the peak in activity (proportion of nights with detections, 0.31) occurring in October.

Mitigation obligations have been met for three of the four Covered Species. The 'ōpe'ape'a baseline (Tier 1) and Higher level of take (Tier 2) mitigation funding obligations were met prior to this fiscal year; current estimated take remains within Higher levels of take (Tier 2). In FY 2023, both USFWS and DOFAW provided concurrence that the Tier 1 mitigation obligation for the 'a'o had been met

based on outcomes of the 2022 breeding season at Makamaka'ole. To date, KWP I has not had observed take of the 'a'o. USFWS provided concurrence that the Tier 2 mitigation obligation had been met for the 'ua'u based on outcomes of the 2022 breeding season on Lāna'i; KWP I awaits similar documentation from DOFAW. KWP I's nēnē current estimate of take remains within Tier 1. Tier 1 mitigation is ongoing as propagation efforts at the Haleakalā Ranch nēnē release pen. KWP I is exploring opportunities for additional mitigation projects to address lagging mitigation credits.

KWP I communicated actively with USFWS and DOFAW throughout FY 2023. The communication was conducted through conference calls, submittal of quarterly reports, and email communications related to the Project's HCP. The purpose of these communications included required semi-annual and annual HCP implementation meetings and focused discussions of all components of mitigation.

## 1.0 Introduction

The Hawaii Department of Land and Natural Resources (DLNR), Division of Forestry and Wildlife (DOFAW) and U.S. Fish and Wildlife Service (USFWS) approved the Kaheawa Wind Project I (Project) Habitat Conservation Plan (HCP) in 2006. Kaheawa Wind Power, LLC (KWP I) was issued a federal Incidental Take Permit (ITP; ITP- TE118901-1) from the U.S. Fish and Wildlife Service (USFWS) and a state Incidental Take License (ITL; ITL-08) from the DLNR in January of 2006. The ITP and ITL cover the incidental take of four federally and state-listed threatened and endangered species (referred to as the Covered Species) over a 20-year permit term.

The Covered Species include the:

- ‘Ōpe‘ape‘a (Hawaiian hoary bat; *Lasiurus cinereus semotus*);
- Nēnē (Hawaiian goose; *Branta sandvicensis*);
- ‘Ua‘u (Hawaiian petrel, *Pterodroma sandwichensis*); and
- ‘A‘o (Newell’s shearwater, *Puffinus newelli*).

The HCP frames take levels and mitigation as “Baseline Take” and “Higher Take.” Hereafter, this document refers to Baseline Take as Tier 1 and Higher Take as Tier 2.

The Project was constructed in 2005 and 2006 and was commissioned to begin operating on June 22, 2006. Brookfield Renewable Partners, LP acquired the Project’s LLC through acquisition of a controlling interest TerraForm, LLC in 2017; the Project continues to be operated by KWP I.

On behalf of KWP I, Tetra Tech, Inc. (Tetra Tech) prepared this progress report to describe the work performed for the Project during the State of Hawai‘i 2023 fiscal year (FY 2023; July 1, 2022 – June 30, 2023) pursuant to the terms and obligations of the approved HCP, ITL, and ITP. KWP I has previously submitted annual HCP progress reports for FY 2007 through FY 2022 to the USFWS and DOFAW (KWP I 2007, KWP I 2008, KWP I 2009, KWP I 2010, KWP I 2011, KWP I 2012, KWP I 2013, KWP I 2014, KWP I 2015, KWP I 2016, KWP I 2017, KWP I 2018, Tetra Tech 2019, Tetra Tech 2020, Tetra Tech 2022a, Tetra Tech 2022b).

## 2.0 Fatality Monitoring

The Project has implemented a year-round intensive fatality monitoring program to document downed (i.e., injured or dead) wildlife incidents involving Covered Species and other species at the Project since operations began in June 2006. In consultation with USFWS, DOFAW, and the Endangered Species Recovery Committee (ESRC), fatality search areas have evolved over time from the start of operations through the initiation of the current approach established in April 2015. The last modifications were in response to the March 31, 2015, ESRC meeting, wherein members agreed to “encourage the applicant to work with the statistical experts and researchers to develop an alternative more efficient and focused monitoring strategy which still meets the committee’s

expressed preference for continuation of annual monitoring.” The evolution of the searched areas in which fatality monitoring occurred (search plots) included:

- In June 2006, search plots were 180-meter by 200-meter rectangles centered on each of the Project’s 20 wind turbine generators (WTG).
- On October 1, 2010, search plots were reduced to 73-meter radius circular plots centered on each WTG, except where steep slopes prohibited visual searching.
- Since April 2015, search plots were reduced to the graded WTG pads and access roads that fall within a 70-meter radius circle centered on each of the Project’s 20 WTGs (Figure 1). This search area continues to be used for monitoring in FY 2023.

In FY 2023, all 20 WTGs were searched for fatalities once per week. The FY 2023 mean search interval for all WTGs was 7.0 days ( $SD = 0.24$ ). The search plots were searched by a canine search team which included a trained detector dog accompanied by a handler. Should search conditions prevent the use of dogs (e.g., weather, injury, availability of canine search team, etc.), search plots would be visually surveyed by Project staff. In FY 2023, all searches were conducted by canine teams and no visual searches occurred.

Four fatalities of Covered Species were detected in FY 2023. One ‘ōpe‘ape‘a was detected in March 2023 (Section 7.1.1). Three nēnē fatalities were detected; two in January 2023, incidentally during a scheduled search but outside of the defined search area, and one detected in April 2023 during a scheduled search (Section 7.2.1). Fatalities of other species are reported in Section 7.4.

Precautions have been taken to prevent potential canine interactions with wildlife, particularly the nēnē. If nēnē were present in the search area, the canine handler immediately retrieved and restrained the dog, avoided disturbing the birds, postponed searching in the vicinity of the birds, worked on leash away from wildlife and/or temporarily skipped canine searches in the proximity of the nēnē. A total of 50 observations of 111 (non-distinct) individual nēnē were made over 23 days between August 2022 and June 2023. Observations were made in August 2022 and in each month from October 2022 to June 2023. In each case, the canine handler moved the dog to a different WTG search area away from the nēnē and returned to finish the search later in the day. No canine searcher-wildlife interactions occurred in FY 2023.

Figure 1. HCP Implementation Components

### 3.0 Carcass Persistence Trials

Trials used black rats (*Rattus rattus*) for 'ōpe'ape'a surrogates (i.e., small carcass), large chickens (*Gallus gallus*) for nēnē surrogates (i.e., large birds), and wedge-tailed shearwater (*Ardenna pacifica*) carcasses as surrogates for the 'ua'u and the 'a'o (i.e., medium birds; Covered Seabird Species). One 28-day carcass persistence trial was conducted in each quarter of FY 2023, for a total of four trials and 40 carcasses (20 small, 10 medium, and 10 large). For FY 2023, the probability that a carcass persisted until the next search was 0.92 for all bat surrogate carcasses (95 percent Confidence Interval [CI] = 0.86, 0.96; N=20), 1.00 for nēnē surrogates (95 percent CI = 0.97, 1.00; N=10), and 0.99 for seabird surrogates (95 percent CI = 0.89, 1.00; N=10).

### 4.0 Searcher Efficiency Trials

A total of 60 searcher efficiency trial carcasses were placed over 18 trial days during FY 2023. Similar to the carcass persistence trials, black rats were used as surrogates for bats and chickens were used as surrogates for the nēnē. Surveyors used wedge-tailed shearwaters and other medium-sized birds collected under the Project's Special Purpose Utility Permit (MBPER0055564-0, valid through 03-31-2025) and Protected Wildlife Permit (WL21-18, valid through 01-24-2024) as surrogates for Covered Seabird Species. Searcher efficiency trials occurred throughout the year; 100 percent were conducted with canine search teams in FY 2023. Of the 61 trial carcasses placed, one bat surrogate was lost to scavenging. All other carcasses were available for detection. For FY 2023, the probability that a canine search team would find a carcass was 0.95 for bat surrogates (95 percent CI = 0.84, 0.99; N=38), 1.00 for nēnē surrogates (95 percent CI = 0.82, 1.00; N=12), and for 'ua'u surrogates (95 percent CI = 0.78, 1.00; N=10).

### 5.0 Vegetation Management

In order to maximize fatality monitoring efficiency and minimize impacts to native plants without compromising soil stability, KWP I performs vegetation management at the Project. Vegetation management activities have evolved over time, and account for management activity restrictions during the nēnē nesting season. The evolution of activity includes:

- Initial vegetation management activities within the search plots were limited to between April 1 and October 31 to minimize risk during the nēnē nesting season.
- In November 2016, Stephanie Franklin of DOFAW-Maui verbally approved using hand management tools (spray packs and weed whackers) during the nēnē nesting season if the activity was within the current search area and did not disturb wildlife.
- In March 2017, Stephanie Franklin of DOFAW-Maui verbally approved the removal of Christmas berry (*Schinus terebinthifolius*) within 70 meters of the WTGs to reduce potential nēnē nesting habitat in the vicinity.

- In September 2021, Stephanie Franklin of DOFAW-Maui verbally approved the continuation of the quarterly management program and woody vegetation removal using hand and power tools, and manual application of herbicide on cut stumps as necessary, in proximity to select turbines. Additional woody vegetation removal was approved to occur within a one-meter buffer of select turbine access roads with all work completed between April 1 and October 31 and in conjunction with a biological monitor.

In FY 2023, vegetation management was implemented at the Project in Q1, Q2, and Q4. During these quarters, glyphosate-based herbicide treatments using a boom sprayer were applied to the cleared areas within each search plot, supplemented by weed whacking to maintain consistency of the extent of the cleared area within 70 meters of each WTG. In each quarter that vegetation management occurred, the herbicide was applied after the areas were deemed clear of nēnē activity by a biological monitor. Additionally, in Q1, woody vegetation removal in the vicinity of WTG 14 was conducted. Target species for removal included ironwood (*Casuarina equisetifolia*), Christmas berry, lantana (*Lantana camara*), and koa haole (*Leucaena leucocephala*) using cut stump/basal treatment methods. Additionally, all debris piles were removed and scattered with the use of a woodchipper onsite.

## 6.0 Scavenger Trapping

KWP I implements periodic scavenger trapping at the Project to extend carcass persistence times and contribute to a high probability of a carcass persisting until the next search. The program includes a once-quarterly intensive trapping effort followed by ongoing biweekly (every other week) trapping effort. In FY 2023, trapping included the use of 24 DOC250 body grip traps and 18 live traps placed throughout the Project. This level of effort is consistent with the increased level of effort employed in FY 2022 and resulted in an average of 40 trap nights per quarter for cage traps, and 91 trap nights per quarter for the DOC250s. In FY 2023, the scavenger trapping program removed 30 mongooses (*Herpestes auropunctatus*), and three feral cats (*Felis catus*). No non-target animals were trapped. This program also benefits the resident wildlife, including the nēnē, by reducing the potential for predation.

## 7.0 Documented Fatalities and Take Estimates

Four fatalities of Covered Species were detected in FY 2023. One 'ōpe'ape'a was detected in March 2023 (Section 7.1.1). Three nēnē fatalities were detected, with two incidental finds outside of the defined search area in January 2023 and one detected during a scheduled search and within the defined search plot in April 2023. All observed downed wildlife were handled and reported in accordance with the Downed Wildlife Protocol provided by USFWS and DOFAW (USFWS and DOFAW 2020). No injured (live) downed wildlife was observed at the Project in FY 2023.

To calculate take estimates, the number of observed fatalities is scaled to account for fatalities that are not detected (unobserved). Unobserved fatalities are the result of three primary factors:

- Carcasses may be scavenged before searchers can find them;
- Carcasses may be present, but not detected by searchers; and
- Carcasses may fall outside of the search area.

Carcass persistence and searcher efficiency (bias correction; see Sections 3.0 and 4.0) measure the effect of the first two factors. The third factor, the number of carcasses that fall outside of the search plot area, is dependent upon the proportion of the carcass distribution that is searched. The search area for fatalities at the Project has evolved over time (Section 2.0); therefore, the proportion of the carcass distribution searched has varied historically. As no changes to search plot dimensions have been made since FY 2016, the estimate of the density weighted proportion (DWP) of the carcass distribution searched (Appendix 1) has remained the same as described in the FY 2017 annual report (KWP I 2017).

Cumulative take at an upper credible limit (UCL) of 80 percent was calculated for each Covered Species for which documented fatalities have occurred, per request of USFWS and DOFAW. The UCL is estimated from three components:

1. Observed direct take (ODT) during protocol (standardized) fatality monitoring;
2. Estimated Unobserved direct take (UDT); and
3. Estimated Indirect take.

The Evidence of Absence software program (EoA; Dalthorp et al. 2017), the agency-approved analysis tool for estimating direct take, uses results from bias correction trials and ODT to generate a UCL of direct take (i.e., ODT + UDT). Direct take values from this analysis can be interpreted as: there is an 80 percent probability that actual direct take at the Project over the analysis period was less than or equal to the 80 percent UCL. Indirect take calculations are based on the HCP (KWP I 2006) and agency guidance. Indirect take is estimated based on factors such as the breeding season in which fatalities are observed, sex and age characteristics of Covered Species fatalities found at the Project, their associated life history characteristics as described in the Project's approved HCP, and current agency guidance for the 'ōpe'ape'a (e.g., USFWS 2016).

Additionally, EoA includes a module that allows users to project future estimates of mortality based on results of past fatality monitoring. Due to the inherent uncertainty of these projections (including the potential future contribution of indirect take) and the amplification of this uncertainty resulting from the use of the 80 percent UCL as the estimate of take for regulatory compliance, long term projections may have limited utility. Nevertheless, they do help gauge the likelihood of permit take exceedance, and may help operators in their mitigation planning, assuming future management and monitoring conditions can be reasonably estimated.

## 7.1 ‘Ōpe‘ape‘a

### 7.1.1 *Estimated Take*

A total of 13 ‘ōpe‘ape‘a fatalities have been observed at the Project since monitoring began in June 2006. Of the 13 observed, 10 were found inside of fatality search plots and are used to estimate UDT. Three bat fatalities were classified as incidental observations. All bat carcasses prior to FY 2023 were transferred to the U.S. Geological Survey for genetic sexing. Genetic sexing is used to refine estimates of indirect take. On March 28, 2023, one adult male<sup>1</sup> ‘ōpe‘ape‘a carcass was observed during a scheduled search 1 meter from Turbine 16. The carcass was fresh with no visible signs of trauma and, following permission from DOFAW Maui, was stored in an onsite freezer until being transferred to DOFAW Maui personnel on April 5, 2023. This fatality occurred under the implementation of Low Wind Speed Curtailment (LWSC; see Section 10.0).

The observed ‘ōpe‘ape‘a fatalities by fiscal year are listed in Table 1.

**Table 1. Observed ‘Ōpe‘ape‘a Fatalities at KWP I Through FY 2023**

| <b>Fiscal Year</b> | <b>‘Ōpe‘ape‘a Observed Direct Take</b> | <b>‘Ōpe‘ape‘a Incidental Fatality Observations</b> | <b>Total</b> |
|--------------------|--|--|--------------|
| 2007               | 0                                      | 0  | 0            |
| 2008               | 0                                      | 0  | 0            |
| 2009               | 0                                      | 1  | 1            |
| 2010               | 0                                      | 0  | 0            |
| 2011               | 0                                      | 1  | 1            |
| 2012               | 0                                      | 0  | 0            |
| 2013               | 2                                      | 0  | 2            |
| 2014               | 4                                      | 0  | 4            |
| 2015               | 0                                      | 0  | 0            |
| 2016               | 0                                      | 0  | 0            |
| 2017               | 1                                      | 1  | 2            |
| 2018               | 1                                      | 0  | 1            |
| 2019               | 1                                      | 0  | 1            |
| 2020               | 0                                      | 0  | 0            |
| 2021               | 0                                      | 0  | 0            |
| 2022               | 0                                      | 0  | 0            |
| 2023               | 1                                      | 0  | 1            |
| <b>Total</b>       | <b>10</b>                              | <b>3</b>   | <b>13</b>    |

<sup>1</sup> Sex determined based on visible external genitalia.

The estimated direct take (ODT + UDT) for the 13 ‘ōpe‘ape‘a fatalities found between the start of fatality monitoring in June 2006 and end of FY 2023 (June 30, 2023) is less than or equal to 28 bats (80 percent UCL; Appendix 1a).

Indirect take is estimated to account for the potential loss of individuals (offspring) that may occur indirectly as the result of the loss of an adult (breeding) female through direct take during the period that females may be pregnant or supporting dependent young. The seasonal timing and sex of all observed fatalities (those observed in fatality monitoring as well as incidental to fatality monitoring) is used in the estimate of indirect take. Cumulative indirect take is calculated as 3.17 adults (Appendix 2a).

The UCL for cumulative Project take of the ‘ōpe‘ape‘a at the 80 percent credibility level is 32 adult bats (28 [estimated direct take] + 4 [estimated indirect take, rounded up from 3.17]). That is, there is an approximately 80 percent probability that cumulative take at the Project at the end of FY 2023 is less than or equal to 32 bats (Appendix 1a).

### **7.1.2 Projected Take**

KWP I projected ‘ōpe‘ape‘a take through the end of the permit term using the fatality monitoring data collected through FY 2023. The objective of this analysis was to evaluate the potential for the Project to exceed the permitted take limit at the 80 percent UCL prior to the end of the permit term (Appendix 3). For this analysis, the detection probability for future years is conservatively assumed to match the detection probability of FY 2021 (0.436; 95 percent CI 0.354, 0.521), and the fatality rate is unaltered for all future years ( $\rho=1$ ). Future indirect take is unknown and will potentially vary based on the timing of ODT. Based on historical Project data, KWP I assumed total indirect take for the Project over the permit term would be a maximum of six adult equivalents (approximately 20 juveniles based on assumed ‘ōpe‘ape‘a survival rates; USFWS 2016), or 12 percent of the permitted take. Currently, the proportion of total take that is attributable to indirect take is roughly 10.2 percent ( $3.17 \text{ [adult bat equivalents estimated from indirect take]} / 31.17 \text{ [bats estimated combining the direct and indirect take]}$ ), making the assumption of indirect take of six adult bats conservative. Assuming six adult bat equivalents are attributed to the Project as indirect take, the permitted direct take under the Project’s ITP and ITL would be 44 bats (50 bats [permitted by ITL and ITP] minus 6 bats [estimated as attributed to indirect take] = 44 bats estimated direct take maximum).

Based on the analysis, there is an approximately 99.3 percent probability that the 80 percent UCL of cumulative take at the Project *will not* exceed permitted Tier 2 take during the permit term (Appendix 3). EoA projected a median estimate of 20 years of Project operation without a direct take estimate exceeding 44 bats. Therefore, based on these projections the Project is likely to remain below the permitted take limit of 50 ‘ōpe‘ape‘a for the permit term.

## 7.2 Nēnē

### 7.2.1 Estimated Take

A total of 34 nēnē fatalities attributable to the Project have been observed at the Project since monitoring began in June 2006. Twenty-seven of the 34 geese were found inside of fatality search plots and are used to estimate direct take, while seven were considered incidental detections. The observed nēnē fatalities by fiscal year are listed in Table 2.

**Table 2. Observed Nēnē Fatalities at KWP I Through FY 2023**

| <b>Fiscal Year</b>   | <b>Nēnē Observed Direct Take</b> | <b>Nēnē Incidental Fatality Observations</b> | <b>Total</b> |
|--|----------------------------------|--|--------------|
| 2007   | 0                                | 0  | 0            |
| 2008   | 2                                | 1  | 3            |
| 2009   | 1                                | 0  | 1            |
| 2010   | 1                                | 0  | 1            |
| 2011   | 5                                | 0  | 5            |
| 2012   | 1                                | 0  | 1            |
| 2013   | 4                                | 0  | 4            |
| 2014   | 3                                | 0  | 3            |
| 2015   | 4                                | 0  | 4            |
| 2016   | 1                                | 0  | 1            |
| 2017   | 0                                | 1  | 1            |
| 2018   | 1                                | 1  | 2            |
| 2019   | 2                                | 0  | 2            |
| 2020   | 0                                | 0  | 0            |
| 2021   | 0                                | 2 <sup>1</sup>                               | 2            |
| 2022   | 1                                | 0  | 1            |
| 2023   | 1                                | 2  | 3            |
| <b>Total</b>   | <b>27</b>                        | <b>7</b>                                     | <b>34</b>    |
| 1. Includes one juvenile fatality found outside of search area. Based on estimated age and carcass condition at discovery, it is unknown if carcass was attributed to Project operations or other circumstances. |                                  |  |              |

On January 3, 2023, one adult nēnē carcass was incidentally observed during a scheduled search 44 meters from Turbine 17 but outside of the cleared search area (Figure 1). On January 17, 2023, one adult nēnē carcass was incidentally observed during a scheduled search 43 meters from Turbine 7, again outside of the cleared search area. On April 25, 2023, one adult nēnē carcass was observed during a scheduled search 10 meters from Turbine 16.

The estimated direct take (ODT + UDT) for the 27 nēnē fatalities (within the search area) found between the start of operation (June 5, 2006) and end of FY 2023 (June 30, 2023) is less than or equal to 52 geese (80 percent UCL; Appendix 1b).

Indirect take is estimated to account for the potential loss of individuals that may occur as the result of the loss of their parents. Both parents care for young post-fledging (Banko et al. 2020). The point during the breeding season when an adult is taken determines to what extent offspring may be affected. Cumulative indirect take was 3.43 juveniles (1.76 adults, assuming a 0.8 annual survival rate and 3 years from fledging to adult; Appendix 2b).<sup>2</sup>

The UCL for cumulative Project take of the nēnē at the 80 percent credibility level is 54 geese (52 [estimated direct take] + 2 [estimated indirect take, rounded up from 1.76]). That is, there is an approximately 80 percent probability that cumulative take at the Project at the end of FY 2023 is less than or equal to 54 adult geese.

In FY 2022 Brookfield's Kaheawa II Wind Project (KWP II), USFWS, and DOFAW reached consensus on mitigation credits attributable to the Project through FY 2021; however, consensus has not been reached on mitigation credit through FY 2023. The total mitigation credits assigned through FY 2021 are distributed annually as indicated in rows K and L of Appendix 2b, as agreed to in FY 2022. Per the HCP, the Project may cause a net loss in productivity in the event that take outpaces the number of individuals produced from mitigation efforts. The lag between production of geese through mitigation efforts and the take of geese at the Project drive the estimates of lost productivity. Accrued lost productivity at a given point in time is calculated as the cumulative take less the number of individuals generated from mitigation efforts to date, and then adjusted by a factor of 0.1 to account for the probability that those unmitigated birds would have produced young (KWP 2006). USFWS and DOFAW have agreed that the Project will not accrue lost productivity for nēnē take that occurred prior to calendar year 2011, the year the release pen was constructed. Six nēnē fatalities were documented at the Project prior to January 1, 2011. Accrued lost productivity is not currently calculable without mitigation credit data, an assessment of which will be determined in consultation with agencies.

### **7.2.2 Projected Take**

KWP I projected nēnē take through the end of the permit term using the fatality monitoring data collected through FY 2023. The objective of this analysis was to evaluate the potential for the Project to exceed the Tier 1 take limit (described as Baseline Take in the Project's HCP) at the 80 percent UCL prior to the end of the permit term (Appendix 3). For this analysis, the detection probability for future years is assumed to match the estimated overall detection probability of FY 2021 (0.336; 95 percent CI 0.315, 0.357), and the fatality rate is unaltered for all future years ( $\rho=1$ ). Future indirect take is unknown and will potentially vary based on the timing of ODT. Based on historical Project data, KWP I assumed total indirect take for the Project over the permit

---

<sup>2</sup> No indirect take was attributed to the observed juvenile fatality observed in FY 2021, as a juvenile could not have dependent young.

term would be a maximum of two adult equivalents (approximately four juveniles based on an assumed nēnē survival rate from juvenile to adult of 0.512; KWP I 2006), or 3.3 percent of the Tier 1 take. Currently, the proportion of total take that is attributable to indirect take is 3.3 percent (1.76 [adult goose equivalents estimated from indirect take]/ 53.76 [adult geese estimated, combining the direct and indirect take]), making the assumption of two indirect take on par with the data. Assuming two adult nēnē are attributed to the Project as indirect take, the permitted direct take under Tier 1 of the Project's ITP and ITL would be 58 nēnē (60 geese [permitted by ITL and ITP for Tier 1] minus 2 geese [estimated attributed to indirect take] = 58 geese estimated direct take maximum).

Based on the analysis described above, there is a 24.5 percent chance that the 80 percent UCL of cumulative take *will not* exceed the Tier 1 take limit during the permit term (Appendix 3). EoA projected a median estimate of 20 years of Project operation without a direct take estimate exceeding 58 geese. Estimated take at the 80 percent UCL at the Project has surpassed 75 percent of allowable take in the current tier take and KWP I has consulted with agencies throughout FY 2023 regarding adjustments to the mitigation program needed to meet obligations, including the required process authorizing Tier 2 level of take (described as Higher Take) and clarification of the regulatory standard for measuring take as it is applied to KWP I.

Finally, KWP I has taken actions to minimize the threats to the nēnē at the Project and anticipates continuing to work with USFWS, DOFAW, and technical experts to further reduce risks of take (Sections 5.0, 10.0).

## 7.3 'Ua'u

### 7.3.1 Estimated Take

A total of eight 'ua'u fatalities have been observed at the Project since monitoring began in June 2006. Seven of the eight petrels were found inside of fatality search plots and were used to estimate direct take. The FY 2013 fatality was found outside of the designated search areas and is treated as an incidental observation. The observed 'ua'u fatalities by fiscal year are listed in Table 3.

**Table 3. Observed 'Ua'u Fatalities at KWP I Through FY 2023**

| Fiscal Year | 'Ua'u Observed Direct Take | 'Ua'u Incidental Fatality Observations | Total |
|-------------|----------------------------|--|-------|
| 2007        | 0                          | 0                                      | 0     |
| 2008        | 1                          | 0                                      | 1     |
| 2009        | 0                          | 0                                      | 0     |
| 2010        | 0                          | 0                                      | 0     |
| 2011        | 0                          | 0                                      | 0     |
| 2012        | 2                          | 0                                      | 2     |
| 2013        | 0                          | 1                                      | 1     |
| 2014        | 1                          | 0                                      | 1     |

| <b>Fiscal Year</b> | <b>‘Ua‘u Observed Direct Take</b> | <b>‘Ua‘u Incidental Fatality Observations</b> | <b>Total</b> |
|--------------------|-----------------------------------|---|--------------|
| 2015               | 2                                 | 0   | 2            |
| 2016               | 0                                 | 0   | 0            |
| 2017               | 0                                 | 0   | 0            |
| 2018               | 0                                 | 0   | 0            |
| 2019               | 1                                 | 0   | 1            |
| 2020               | 0                                 | 0   | 0            |
| 2021               | 0                                 | 0   | 0            |
| 2022               | 0                                 | 0   | 0            |
| 2023               | 0                                 | 0   | 0            |
| <b>Total</b>       | <b>7</b>                          | <b>1</b>                                      | <b>8</b>     |

The estimated direct take (ODT + UDT) for the seven ‘ua‘u fatalities found between the start of operation (June 5, 2006) and end of FY 2023 (June 30, 2023) is less than or equal to 18 petrels (80 percent UCL; Appendix 1c).

Indirect take is estimated to account for the potential loss of individuals that may occur as the result of the loss their parents. Both parents for the ‘ua‘u care for their young until fledging. The point during the breeding season when an adult is taken determines to what extent offspring may be affected. Cumulative indirect take was calculated at 13.59 juveniles (4.08 adults assuming a 0.3 survival rate from fledging to adult; Appendix 2c).

The Project may cause a net loss in productivity if take outpaces the number of individuals produced from mitigation efforts. The life history lag between production of the ‘ua‘u through mitigation efforts and the take of petrels at the Project drives the estimates of lost productivity. Accrued lost productivity at a given point in time is calculated as the cumulative take less the number of individuals generated from mitigation efforts to date, and then adjusted by a factor of 0.15 to account for the probability that those unmitigated petrels would have produced young (KWP I 2006). Each year’s lost productivity is accumulated until mitigation occurs for the estimated adult take. Lost productivity information is provided in Appendix 2c.

The UCL for cumulative Project take of the ‘ua‘u at the 80 percent credibility level is 23 petrels (18 [estimated direct take] + 5 [estimated indirect take, rounded up from 4.08]). That is, there is an approximately 80 percent probability that cumulative take at the Project at the end of FY 2023 is less than or equal to 23 petrels.

### **7.3.2 Projected Take**

KWP I projected ‘ua‘u take through the end of the permit term using the fatality monitoring data collected through FY 2023. The objective of this analysis was to evaluate the potential for the Project to exceed the permitted take limit at the 80 percent UCL prior to the end of the permit term

(Appendix 3). For this analysis, the detection probability for future years is assumed to match the estimated overall detection probability of FY 2023, and the fatality rate is unaltered for all future years ( $\rho=1$ ). Future indirect take is unknown and will potentially vary based on the timing of ODT. Based on historical Project data, KWP I assumed total indirect take for the Project over the permit term would be a maximum of eight adult equivalents (approximately 27 juveniles based on an assumed 'ua'u survival rate of 0.3 from fledging to adult; KWP I 2006), or 21.1 percent of the permitted take. Currently, the proportion of total take that is attributable to indirect take is 18.5 percent (4.08 [adult petrel equivalents estimated from indirect take]/ 22.08 [adult petrel estimated combining the direct and indirect take]), making the assumption of eight indirect take upwardly conservative.

Assuming eight adult 'ua'u equivalents are attributed to the Project as indirect take, the permitted direct take under the Project's ITP and ITL would be 30 petrels (38 petrels [permitted by ITL and ITP] minus 8 petrels [estimated to be attributed to indirect take] = 30 'ua'u estimated direct take maximum).

Based on the analysis described above and presented in Appendix 3, there is a 99.88 percent chance that the 80 percent UCL of cumulative take *will not* be exceeded during the permit term. Specifically, the estimated direct take threshold of 30 exceeds more than 99 percent of the projected mortality estimates (Appendix 3). EoA projected a median estimate of 20 years of Project operation without a direct take estimate exceeding 30 petrels. Therefore, the Project is likely to remain below the permitted take limit of 38 'ua'u for the permit term.

## **7.4 Non-listed Species**

In addition to the three nēnē fatalities and one 'ōpe'ape'a fatality, six non-listed bird fatalities representing four species were documented at WTGs at the Project in FY 2023. One of the four species observed in FY 2023 is protected by the Migratory Bird Treaty Act (MBTA): the northern mockingbird (*Mimus polyglottos*, one individual). Five fatalities of three non-native (introduced) species without MBTA protection were also detected: the black francolin (*Francolinus francolinus*; three individuals), gray francolin (*Francolinus pondicerianus*; one individual), and warbling white-eye (*Zosterops japonicus*; one individual). For a complete list of fatalities for FY 2023, see Appendix 4.

## **8.0 Wildlife Education and Observation Program**

The wildlife education and observation program (WEOP) helps to ensure the safety and well-being of native wildlife in work areas and along site access roadways. The training provides useful information to assist staff, contractors, and visitors to be able to conduct their business in a manner consistent with the requirements of the HCP, the Conditional Use Permit, land use agreements and applicable laws. Personnel are trained to identify Covered Species and other species of wildlife that may be found on-site and what protocol to follow, as determined in the HCP and through relevant agency guidance (e.g., USFWS and DOFAW 2020), when downed wildlife is found. The trainees are

also made aware of driving conditions and receive instruction on how to drive and act around wildlife. Records of wildlife observations by WEOP-trained staff are also used by the HCP program to identify the patterns of wildlife use of the site.

WEOP trainings were provided over 6 dates in FY 2023 training total of 29 people. WEOP trainings will continue to be conducted on an as-needed basis to provide on-site personnel with the information to respond appropriately in the event they observe a Covered Species or encounter downed wildlife while on-site.

## **9.0 Mitigation**

The Project's mitigation requirements are described in Section 5.0 of the approved HCP (KWP I 2006).

### **9.1 'Ōpe'ape'a**

#### ***9.1.1 Mitigation***

Mitigation for Tier 1 take of 20 bats was funded in 2006 and completed. An HCP minor amendment approved by USFWS in October 2015 and DOFAW in January 2016 authorized take of up to an additional 30 'ōpe'ape'a under Tier 2 which had been identified in the HCP but not included on the ITP and ITL.

A mitigation project that mitigates for 15 of the additional 30 bats began May 2017 and was completed in FY 2020 (KWP I 2017, Tetra Tech 2020). This mitigation project consisted of 'ōpe'ape'a ecological research in East Maui, contracted to H.T. Harvey Ecological Consultants. The contract total cost was \$750,000.

Mitigation funding for the remaining 15 bats in Tier 2 was provided to the U.S. Geological Survey Hawaiian Hoary Bat Research Group starting in FY 2018 to conduct bat ecological research on Hawai'i Island to better inform future bat habitat restoration and conservation. The funding obligation was completed in FY 2022 and the research project is expected to be completed in December 2023 with final publication, technical results, and data releases. The Project, in combination with KWP II, had a total funding obligation of \$1.7M to allocate to portions of each Project's mitigation requirement. KWP I, in combination with KWP II exceeded this funding obligation by \$131,500 over the original cost, for a total combined expenditure of \$1,831,500.

#### ***9.1.2 Acoustic Monitoring at the Project***

Acoustic monitoring for bat activity at the Project has been conducted continuously since August 2008. Acoustic monitoring after the HCP-required initial 12-month period is a voluntary measure. In October 2013 (FY 2014), nine Song Meter SM2BAT+ ultrasonic recorders (SM2) were deployed, replacing the previously used Anabat SD2 bat detectors (Titley Electronics, Brendale, QLD, Australia). Each SM2 was equipped with one SMX-U1 ultrasonic microphone (Wildlife Acoustics,

Maynard, MA, USA) positioned horizontally, facing southwest (away from the prevailing northeast trade winds), 6.5 meters above ground level. In October 2019 (FY 2020), the Pali brush fires burned across most of the Project, destroying four SM2 units. In order to continue with the objectives of the monitoring program and address gaps in the spatial coverage of SM2's introduced by the brush fire, the monitoring regime was redesigned in July 2020 with the deployment of five SM2 units (WTGs 1, 5, 13, 15, and 20; Figure 1). This type of unit has been continuously used since October 2013. Additionally, because of differences in the equipment used prior to FY 2014, data collected in FY 2023 is only comparable to data collected between FY 2014 and FY 2022.

The objective of bat acoustic monitoring is to better understand the annual and seasonal variation in bat activity at the Project. Analysis of variance (ANOVA) and a Tukey's Honest Significant Difference (HSD) post-hoc test were used to test for interannual differences in detection rates between sampling years. A linear model (LM) was constructed to test for a change in detection rates across all sampling years. FY 2014 was removed from the analysis because it did not represent a full sampling year and excluded months known to have high detection rates (July, August, and September). All data were normalized with an Ordered Quantile Normalization transformation using the 'bestNormalize' package in R (Peterson 2021). The distribution of residuals from the LM were examined to check for violations of model assumptions. All tests were two-tailed, employed an alpha value of 0.05, and were conducted in R version 4.2.3 (R Core Team 2023).

Over the course of the FY 2023 monitoring period (July 2022 to June 2023), the 'ōpe'ape'a were detected on 214 nights out of 1,778 detector-nights sampled (12.0 percent, Table 4). Detection rates were highest between the months of August and October during the lactation and post-lactation reproductive periods<sup>3</sup>, with the peak in activity (proportion of nights with detections) occurring during the month of October (0.31, Figure 2). Following the initial peak in October, detection rates fluctuated monthly (between 0.06 and 0.09) throughout the post-lactation and pre-pregnancy reproductive periods (November to March). Detection rates slightly increased in April and May (0.13 and 0.12), at the beginning of the pregnancy reproductive period, followed by subsequent decline and the lowest detection rates (0.01) in July (Figure 2). The temporal pattern in detection rates during FY 2023 were similar to the detection rates observed in FY 2022 (Figure 3). However, the annual trend in detection rates observed in FY 2022 and FY 2023 differs from the bimodal trend observed among previous monitoring years (Figure 3). Detection rates during the lactation and first half of the post-lactation reproductive periods were within range of detection rates observed among the previous sampling years. The cause(s) for the larger January peak observed in FY 2022 and FY 2023 are unknown.

Throughout the FY 2015 – FY 2023 dataset of the Project's monitoring program, there were only marginal fluctuations in the interannual detection rates (Table 4). Across analyzed monitoring years, there is an increasing trend in the annual detection rates. Although the annual detection rates in FY 2023 were greater than FY 2022 (by 2.5 percent), they were not significantly different (ANOVA:  $F_{8,99} = 2.2$ ,  $P < 0.033$ ; Tukey's HSD:  $P > 0.999$ ). Furthermore, the more conservative Tukey's HSD post-hoc analysis, which accounts for accumulated type I errors in the ANOVA (Tian et

al. 2018), found no significant differences in annual detection rates among any years between FY 2015 and FY 2023 (Tukey's HSD:  $P > 0.143$ ). Overall, across analyzed monitoring years (FY 2015 – FY 2023), there is a significant increasing trend in the annual detection rates (LM:  $R^2 = 9.05$  percent;  $F_{1,106} = 10.55$ ,  $P^3 < 0.002$ ; Figure 4).

## 9.2 Nēnē – Haleakalā Ranch Release Pen

In 2009, the Project provided \$264,000 to DOFAW to fund construction and management of the Haleakalā Ranch nēnē release pen as part of Project nēnē mitigation. DOFAW completed construction of the release pen three years later. Funding has been used by DOFAW to perform fence maintenance, predator control, vegetation management, and monitoring at the Haleakalā Ranch pen. Nēnē have been translocated from Kaua'i to the Haleakalā Ranch pen since 2011, and several potential benefits have accrued based on the effects of these actions including production of fledglings and increases adult survival rates.

<sup>5</sup> Ordered Quantile normalization transformation (ORQ). All data were normalized using this transformation.

In May 2020, the Project provided \$140,852 to DOFAW to fund nēnē mitigation activities performed by DOFAW at the Haleakalā Ranch release pen. Receipt of this amount was acknowledged via email by L. Taylor (DOFAW) on June 10, 2020. On August 27, 2021, A. Siddiqi (DOFAW) notified the Project via email that current funding of \$114,863 was available for the Haleakalā Ranch release pen which should last for 23 months if the management effort continued with the same staff and assumed full time. KWP I assumed management of the Haleakalā Ranch release pen in mid-December 2022 while KWP I, KWP II and DOFAW worked toward agreement on an MOU for this management. On July 12, 2023, K. McEachern (DOFAW) notified the Project via email that DOFAW has used only \$26,432.74 of KWP I provided funding of \$134,145 between April 1, 2020 and February 28, 2022. This was the first time the Project was notified that previously provided funding was not being used to support predator control and other management actions at the Haleakalā Ranch because the technician could not work due to an injury.

The outcome of the 2021 – 2022 breeding season included 10 fledglings (Appendix 5), while the outcome of the 2022 – 2023 breeding season included 5 fledglings (Appendix 6). Through 2022, DOFAW has confirmed 76 fledglings produced in the pen from the translocated birds. Through FY 2023, a total of 81 fledglings have been produced (see Appendix 2b for quantification of mitigation credits associated with the Project). KWP I will work with DOFAW (inclusive of USFWS) to address funding issues and inconsistencies, and how they translate to the assessment of mitigation credit.

KWP I acknowledges the Project is lagging in mitigation credits, and is working with DOFAW and USFWS to adaptively manage the nēnē mitigation program. Cumulatively, the increases in adult and juvenile survival and productivity achieved by KWP I's mitigation project have not been sufficient to fully offset the mitigation obligations of Tier 1, and challenges in the application of provided funds to performance of mitigation tasks have provided additional limits. KWP I continues to explore and vet potential mitigation opportunities with USFWS and DOFAW to address lagging credits. As previously mentioned, in FY 2023, KWP I assumed Haleakalā Ranch release pen's management tasks in conjunction with the KWP II Wind Project, in lieu of providing direct funding to DOFAW. In FY 2024, KWP I will continue to work with DOFAW and USFWS to adaptively manage nēnē mitigation.

## **9.3 Seabirds**

KWP I is committed to seabird protection and recovery on Maui and Maui Nui. In FY 2023, KWP I completed its mitigation obligation for both 'a'o and the 'ua'u.

### ***9.3.1 'A'o Survey - East Maui***

KWP II funded surveys for potential mitigation sites on east Maui, which were completed in September 2015 (KWP I 2016). These surveys identified potential colony locations, estimated the numbers of birds present, assessed predator activity, and evaluated management feasibility at the colony locations.

### **9.3.2 'Ua'u and 'A'o – Makamaka'ole**

Mitigation efforts at Makamaka'ole began with the construction of the two predator exclosures completed in September 2013. Mitigation efforts at Makamaka'ole involved predator monitoring and trapping, artificial burrow checks and monitoring using game cameras, seabird social attraction using decoys and sound systems, and ongoing maintenance, including vegetation management, of both enclosures.

In 2022, continued mitigation efforts at Makamaka'ole were contracted to Maui Nui Seabird Recovery Project (MNSRP) through the 2022 calendar year breeding season (hereafter, 2022 breeding season). Project staff visited the enclosures with MNSRP to ensure consistent oversight. MNSRP conducted approximately bi-weekly visitations to the site. During these visits, MNSRP staff checked burrows and game cameras for activity, checked traps, conducted vegetation management, and performed repair and maintenance of the predator exclosures.<sup>6</sup>

Seabird breeding activity was assessed using game cameras, burrow scoping, checking for removal or displacement of toothpicks placed at burrow entrances, as well as checks for evidence of visitation including guano, feathers, and scent presence around burrows. During the 2022 breeding season, 22 burrows in Enclosure A were consistently active with 'a'o activity. A burrow is considered consistently active if it produced a chick or an egg, if the 'a'o appeared entering on camera, if there was more than one type of bird activity evidence during more than one burrow check, or if there was evidence of bird presence inside the burrow box at the end of the season (Appendix 7). In Enclosure B, six burrows had primarily 'a'o and limited Bulwer's petrel (*Bulweria bulwerii*) activity with four burrows demonstrating consistent 'a'o breeding activity. A total of 14 burrows had reproductive activity, producing a total of 18 eggs and one fledged chick (Appendix 7).

#### **Mitigation Obligation Completed**

On December 5, 2022, DOFAW provided a letter assessing that after the 2022 breeding season at Makamaka'ole, credit for 148 adults and 2 fledglings translated into 8.53 'a'o mitigation credits for KWP I (in conjunction with KWP II), and that KWP I had completed its mitigation obligation for the 'a'o. On December 8, 2022, USFWS provided a letter assessing credit for 149 adults and 2 fledglings, translating to a 'a'o mitigation credit of 8.54 adult equivalents, and that the mitigation obligation for KWP I (in conjunction with KWP II) had been met.

Brookfield worked with DOFAW throughout FY 2023 to transfer the management of Makamaka'ole to DOFAW. On September 5th, 2023, L. McEachern provided Brookfield with video footage and photos of the fence condition as of August 2023, including estimated costs to repair the existing structure of \$699,505.16, and requested funding from Brookfield in a subsequent meeting. Brookfield is still working internally toward resolution, has requested additional pertinent documentation from DOFAW, and anticipates further discussions with DOFAW. Although

---

<sup>6</sup> After the transfer of management of Makamaka'ole to DOFAW in February 2023, Brookfield became aware that portions of the predator exclosures at the site required repair or replacement. Brookfield will discuss this issue with DOFAW and USFWS during FY 2024 to learn more about the nature and extent of the potential problem.

Makamaka'ole has been managed to benefit the 'ua'u, as well as the 'a'o, no 'ua'u activity has been detected at burrows within the enclosures since 2017.

### **9.3.3 *Lāna'i 'Ua'u Protection Project***

The 'ua'u have not been observed occupying the Makamaka'ole mitigation site since 2017. Therefore, both KWP projects have worked together with USFWS and DOFAW to adaptively manage mitigation efforts for this species to ensure that its mitigation obligations are met.

Beginning in the 2018 'ua'u breeding season, both KWP projects worked with USFWS and DOFAW to adaptively manage 'ua'u mitigation efforts in an interim fashion. As a result of this adaptive management, KWP I provided funding to Pūlama Lāna'i to supplement 'ua'u breeding colony protection efforts on Lāna'i in 2018. The success of this program and difficulties in attracting petrels to Makamaka'ole suggested that both KWP projects could benefit the 'ua'u and make progress on mitigation obligations by continuing support for the Lāna'i petrel breeding program.

From FY 2021 to FY 2023 (two breeding seasons), the two KWP projects adaptively managed their seabird mitigation programs by providing funding to Pūlama Lāna'i. (Appendix 8) For the 2022 breeding season, this effort included predator control as well as burrow monitoring and evaluation in the densely occupied 'ua'u nesting area composed of the four distinct ridges of East Pu'u Ali'i, Kanalo, West Hi'i, and Hi'i Center Ridge (known as the Greater Hi'i area) totaling approximately 150 acres.

Based on mitigation funding, a total of 9 cats and a minimum of 228 rodents were removed from the greater Hi'i area during the 2022 breeding season (Appendix 7). In concurrence on approach with USFWS and DOFAW, the number of fledglings produced in the area was estimated using a standardized sampling design across the colony, developed from a power analysis and assessment completed in partnership with biologists and statisticians with the Zoological Society of San Diego (Schuetz et al. 2020; pers. comm. E. Gosliner, USFWS, October 31, 2022 and P. Radley, DOFAW, November 16, 2022). This estimation used the proportions of inactive, prospecting, and breeding status burrows, along with reproductive success rates of a given area to determine an estimated proportion of burrows with breeding attempts. This information was used to estimate the number of fledglings produced. In the 2022 breeding season, 224 known burrows yielded an outcome of 78 'ua'u chicks above baseline (Appendix 8).

On December March 27, 2023, USFWS provided a letter assessing that after the 2022 breeding season, the total estimated benefit provided for the 'ua'u from breeding colony protection efforts on Lāna'i was 89.20 credits based on a previously agreed upon assessment framework (pers. comm. E. Gosliner, USFWS, October 31, 2022 and P. Radley, DOFAW, November 16, 2022). Additionally, based on 'ua'u activity at Makamaka'ole in 2016 and 2017, in their March 27<sup>th</sup> letter, USFWS approved an estimated benefit for the 'ua'u of 0.56. Thus, the total mitigation benefit achieved across mitigation projects is 89.72 adult 'ua'u for both KWPs. KWP I's Tier 2 'ua'u mitigation obligation per the ITP is 38 'ua'u (including adults, subadults, fledglings, nestlings, and eggs). In the

March 27 letter, USFWS acknowledges that KWP I has met its 'ua'u mitigation obligation. DOFAW has yet to provide similar documentation.

## **10.0 Adaptive Management**

In accordance with the HCP, the Project began implementing LWSC at all WTGs up to wind speeds of 5 meters per second (m/s) on July 29, 2014. LWSC is expected to reduce risk of bat take (Section 7.12). LWSC was increased to 5.5 m/s on August 4, 2014 in response to bat take occurring at the Project and at KWP II on March 13, 2013 and February 26, 2014. Curtailment at 5.5 m/s is in effect from sunset to sunrise, annually, from February 15 through December 15. The Project continues site-wide bat activity assessment via acoustic monitoring after the initial HCP-required 12-month monitoring period (Section 9.1.2).

The Project has previously implemented a variety of actions to minimize risk to the nēnē, which continued in FY 2023. Scavenger trapping efforts implemented at the Project to improve persistence of carcasses during fatality monitoring have likely reduced the risk of predation of the nēnē and safety measures to avoid interactions between nēnē and canine search teams have been identified and are implemented as needed. In response to the current projections of potential take of the nēnē at the Project, KWP I has taken practicable actions to minimize the threats to the nēnē. In FY 2023, KWP I implemented a vegetation management plan developed with concurrence from the agencies reducing the amount of woody vegetation on site. The goal is to minimize the attractiveness of onsite habitat to the nēnē (Section 5.0). KWP I will continue to monitor nēnē activity on site to inform vegetation management success, and continue to work with USFWS, DOFAW, and technical experts to further reduce risk to the species.

## **11.0 Agency Meetings, Consultations, and Visits**

KWP I communicated actively with USFWS and DOFAW throughout FY 2023 through conference calls, submittal of quarterly reports, and email communications related to the Project's HCP. The purpose of these communications included the required annual and semi-annual HCP implementation meetings, ESRC review of the annual report, focused discussions regarding mitigation projects, mitigation credits for the nēnē and seabird mitigation programs, and nēnē mitigation opportunities. A summary of agency coordination is presented in Table 5.

**Table 5. Summary of Agency Coordination and Communication in FY 2023**

| April 24, 2023 | Submittal of FY 2023 Q3 report   | Submitted to DOFAW, USFWS by Tetra Tech |
| May 4, 2023    | Nēnē release pen mitigation projects discussion                              | KWP I, Tetra Tech, DOFAW Maui           |
| May 11, 2023   | Semi-annual HCP implementation review meeting                                | KWP I, Tetra Tech, USFWS, DOFAW         |
| May 31, 2023   | Nēnē release pen mitigation projects discussion                              | Tetra Tech, A. Siddiqi (DOFAW)          |
| June 28, 2023  | Submission of nēnē potential tier transition and Mitigation Obligations memo | Tetra Tech, USFWS, DOFAW                |

## 12.0 Expenditures

Total HCP-related expenditures for the Project in FY 2023 were \$451,708 (Table 6).

**Table 6. HCP-related Expenditures at the Project in FY 2023**

| Category <sup>1</sup>  | Amount           |
|--|------------------|
| Permit Compliance  | \$59,801         |
| Fatality Monitoring  | \$85,387         |
| Acoustic Monitoring for Bats   | \$15,920         |
| Vegetation Management and Scavenger Trapping   | \$78,861         |
| Equipment and Supplies   | \$5,413          |
| Makamaka'ole Mitigation Project <sup>2</sup>   | \$21,165         |
| Lāna'i Hawaiian Petrel Protection Project <sup>2</sup>   | \$140,915        |
| Haleakalā Release Pen <sup>2</sup>   | \$44,246         |
| <b>Total Cost for FY 2023</b>  | <b>\$451,708</b> |
| <p>1. Staff labor costs are included in the overall costs for each category except for Equipment and Supplies.</p> <p>2. Mitigation project are co-funded by KWP I and KWP II.</p> |                  |

| 1. Where two values are represented, the searched area changed within the modeled period. Detection probability represents the cumulative detection for the year. See annual reports for details.<br>2. Cumulative value representing estimate of total direct take from the start of operations through the identified monitoring period at the 80 percent UCL. |      |           |           |                      |        |         |                        |                                       |                         |   |                 |                  |           |         |         |        |       |                 |

| 1. FY 2013 fatality was mistakenly included in previous analyses. Based on the contemporaneous fatality report, the carcass was recovered outside of the designated search plots.<br>2. Where two values are represented, the searched area changed within the modeled period. Detection probability represents the cumulative detection for the year. See annual reports for details.<br>3. Cumulative value representing estimate of total direct take from the start of operations through the identified monitoring period at the 80 percent UCL. |      |           |           |                      |        |                        |                                       |                                      |     |                 |                  |           |         |         |       |       |                 |

### **Appendix 3. ‘Ōpe‘ape‘a, Nēnē and ‘Ua‘u 20-year Projected Take at the Project in FY 2023**

This page intentionally left blank

---

### Appendix 3a. Projected Cumulative Mortality for the 'Ōpe'ape'a at the Project

1. Permitted take for the 'ōpe'ape'a at the Project is 50; however, take as calculated from EoA only includes direct take. To account for indirect take in this figure, an approximate take threshold (T) of 44 is shown, representing authorized bat take (50) minus 6 adult equivalents of indirect take (12.0 percent of the authorized limit). Currently, the proportion of total take that is attributable to indirect take is 10.2 percent.

### Appendix 3b. Projected Cumulative Mortality for the Nēnē at the Project with Tier 1 Threshold

1. Permitted take for Tier 1 of the nēnē at the Project is 60; however, take as calculated from EoA only includes direct take. To account for indirect take in this figure, an approximate take threshold (T) of 58 is shown, representing permitted nēnē take (60) minus 2 adult equivalents of indirect take (3.3 percent of the requested authorized limit). Currently, the proportion of total take that is attributable to indirect take is 3.3 percent.

### Appendix 3c. Projected Cumulative Mortality for the 'Ua'u at the Project

1. Permitted take for the 'Ua'u at the Project is 38; however, take as calculated from EoA only includes direct take. To account for indirect take in this figure, an approximate take threshold (T) of 30 is shown, representing authorized petrel take (38) minus 8 adult equivalents of indirect take (21.1 percent of the authorized limit). Currently, the proportion of total take that is attributable to indirect take is 18.5 percent.

**Appendix 5. Nēnē Monitoring and Predator Control  
Management at Haleakalā Ranch, Maui Annual Report, FY 2022**

**NĒNĒ MONITORING AND PREDATOR CONTROL MANAGEMENT AT  
HALEAKALĀ RANCH, MAUI  
ANNUAL REPORT  
FY 2022 (JULY 1, 2021 through JUNE 30, 2022)**

## **1.0 Introduction**

Since May 2011, the Hawai'i Department of Land and Natural Resources, Division of Forestry and Wildlife (DOFAW), funded by the Kaheawa Wind Power projects, is managing a Nēnē Monitoring and Predator Control Management Program (Program) at Haleakalā Ranch (Ranch), Maui. The purpose of this Program is to establish a population of the endangered Nēnē, or Hawaiian goose (*Branta sandvicensis*) at the Ranch. The Program contributes to the mitigation requirements for the Nēnē as identified in the Kaheawa Pastures Wind Energy Generation Facility (KWP I) and Kaheawa Wind Power II (KWP II) Habitat Conservation Plans (KWP I 2006, SWCA 2011).

This report summarizes the population establishment efforts for FY 2022. This report and the activities described herein are in compliance with the Haleakalā Ranch SHA (Haleakalā Ranch et al. 2019).

## **2.0 Mitigation Actions**

### **2.1 Road Improvement**

*The road to the pen was maintained periodically, as needed, by moving rocks and backfilling holes with dirt and rocks. Approximately, twenty (20) feet of road was repaired this year.*

### **2.2 Nēnē Monitoring**

#### **2.2.1 Sightings**

*Weekly observations and monitoring were conducted throughout the year on the Ranch. Observations of banded and unbanded birds were recorded at the Ranch to monitor movements, distribution, and survival of Nēnē. In FY2022, thirty-one (31) banded birds were sighted at the Ranch. Twenty-nine (29) were wild Maui Nēnē and two (2) were from the Kauai translocation. An island-wide annual Nēnē survey was conducted on September 27, 2012. During this survey, four (4) birds were seen at the Ranch.*

## 2.2.2 Nesting

*During nesting season, records were kept on mated pairs and the gravid levels of females found at the Ranch. Nests found on the Ranch were marked using GPS and checked weekly to determine their status. Nesting activities, nest outcomes, hatching, and fledgling success were recorded for the nesting season.*

*Ten (10) nests were located at the Ranch this year, nine (9) inside the Ranch's open-top release pen and one (1) outside the pen in the water unit. Five (5) of these nests were successful in producing twelve (12) goslings. Ten (10) Nēnē fledged from the Ranch open-top release pen this season.*

**Table 1. Nēnē Nesting Summary for 2021-2022 Breeding Season at Haleakalā Ranch, Maui**

| Total Number of Nests                                 |    |
|---|----|
| Located at the Ranch                                  | 10 |
| Located in open-top pen                               | 9  |
| Successful  | 6  |
| Abandoned   | 1  |
| Depredated  | 0  |
| Failed (unknown reason)                               | 3  |
| Renests   | 0  |
| Total Number of Eggs                                  |    |
| Known   | 27 |
| Depredated  | 0  |
| Abandoned (later scavenged)                           | 1  |
| Salvaged  | 0  |
| Outcome unknown                                       | 14 |
| Hatched   | 12 |
| Total Number of Goslings/Fledglings                   |    |
| Known goslings  | 12 |
| Goslings died (impact injuries)                       | 2  |
| Fledglings fledged from pen (credited for mitigation) | 10 |

## 2.3 Banding

*Fourteen (14) birds were banded this year, ten (10) fledglings and four (4) adults.*

## 2.4 Pen Maintenance

*The open-top pen's fence line was continuously checked and maintained throughout the year with holes being patched as needed. A total of five (5) feet of fence was repaired along the pen. The entire fence line was weeded monthly, as needed, for a total of four and a half (4.5) acres for the year. The water unit was checked monthly, and the pond and automatic waterers were cleaned and maintained monthly. The door on the water unit was replaced, and the rain gutter and gutter screens were replaced.*

## 2.5 Habitat Management

*Short grass habitat was maintained at the open-top release pen. A total of twenty-eight and a quarter (28.25) acres was mowed this year to maintain Nēnē short grass habitat. Twelve and a quarter (12.25) acres of alien vegetation, including lantana, guava, tomato, fireweed, and bur, were also removed.*

## 2.6 Predator Control

*Predator traps were used to control rats, mongoose, feral cats, and dogs that may pose a threat to Nēnē and their nesting sites. Traplines using thirty (30) Tomahawk live traps, thirty (30), and ten (10) A24s were baited and checked at the Ranch throughout the year.*

*This year at the Ranch, eight (8) mongoose were removed through predator trapping. No avian predators were controlled this season on the Ranch. No cats or cat sign were seen at the pen. Rats may likely be more abundant. Wild dogs have been seen on the ranch, but not specifically near the pen.*

**Table 2. Traps Deployed and Predators Removed during 2021-2022 at Haleakalā Ranch, Maui**

| Predator Type Removed | Trap Type               |                   |                |
|-----------------------|-------------------------|-------------------|----------------|
|                       | Tomahawk Live Trap (30) | Sherman Trap (30) | A24 Traps (10) |
| Cats                  | 0                       | 0                 | 0              |
| Dogs                  | 0                       | 0                 | 0              |
| Mongoose              | 8                       | 0                 | 0              |
| Rats                  | 0                       | 0                 | 0              |
| Mice                  | 0                       | 0                 | 0              |

**Table 3. Avian Predator Control during 2021-2022 at Haleakalā Ranch, Maui**

| Predator<br>Type<br>Removed | Control Effort                                     |  |  |
|-----------------------------|--|--|--|
|                             | (Describe Type 1)<br>(Quantify level of<br>effort) | (Describe Type 2)<br>(Quantify level of<br>effort) | (Describe Type 3)<br>(Quantify level of<br>effort) |
| Barn owls                   | 0  | 0  | 0  |
| Cattle egrets               | 0  | 0  | 0  |

## 2.7 Relocations

*No relocations or releases were done this year.*

## 2.8 Injury, Fatalities, Disease

*One (1) adult nene was found at the pen with a broken right wing. It was taken to the vet and later euthanized due to the severity of the injury. Two (2) goslings that died from impact injuries (one (1) to the head and one (1) to the wing) were found during the nesting season.*

## 2.9 Adaptive Management Actions

## 1.0 Introduction

In May 2011, the Hawai'i Department of Land and Natural Resources—Division of Forestry and Wildlife (DOFAW), with funding from the Kaheawa Wind Power I (KWP I) project, established a Nēnē Introduction Program (Program) at Haleakala Ranch (Ranch), Maui. The purpose of this Program was to establish a population of the endangered nēnē, or Hawaiian goose (*Branta sandvicensis*), at the Ranch. The Program contributes to the mitigation requirements for the nēnē as identified in the KWP I and Kaheawa Wind Power II (KWP II; collectively, the Projects) Habitat Conservation Plans (KWP I 2006, SWCA 2019). As part of the Program, Haleakala Ranch, LLC committed to maintaining or improving the Ranch premises, which are considered to provide a significant amount of habitat that may be suitable for nēnē, for renewable periods of 10 years over the 50-year term of the Haleakala Ranch Safe Harbor Agreement (SHA; USFWS et al. 2019). The Program has successfully produced fledglings at the Ranch since 2012.

In 2021, DOFAW requested that the Projects assume direct management of the release pen. While the Projects and DOFAW finalize a Memorandum of Understanding (MOU), both parties have agreed that the Projects assumed management activities on December 8, 2022. The Projects contracted Aloha Environmental Services (AES) to conduct the work as laid out in the SOW, to be appended to the MOU. Key needs for establishing a population of nēnē at the Ranch were identified in the SHA as nest monitoring, pen maintenance, habitat management, and predator control. This report and the activities described herein are in compliance with the Ranch's SHA (USFWS et al. 2019). This report provides detail of the 2022 – 2023 breeding season at the Ranch through the end of Fiscal Year (FY) 2023 (June 30, 2023). Table 1 shows the expenditures during FY 2023.

**Table 1. Expenditures During December 8, 2022 – June 30, 2023**

| <b>Expenditure Type</b>   | <b>KWP I Funded Amount</b> | <b>KWP II Funded Amount</b> |
|---|----------------------------|-----------------------------|
| Road Improvement  | \$5,000                    | \$5,000                     |
| Nēnē Monitoring   | \$4,709.50                 | \$4,709.50                  |
| Pen Maintenance   | \$3,953.50                 | \$3,953.50                  |
| Habitat Management  | \$4,728                    | \$4,728                     |
| Predator Control  | \$8,002                    | \$8,002                     |
| Data Collection, Analysis and Reporting   | \$3,953                    | \$3,953                     |

| <b>Total Cost for FY 2023</b>   | <b>\$30,346.50</b>         | <b>\$30,346.50</b>          |
| 1. Costs for supplemental vegetation clearing required upon the assumption of management responsibilities not quantified (see Section 2.8). |                            |                             |

## 2.0 Mitigation Actions

### 2.1 Road Improvement

The road to the pen was maintained periodically by AES staff, as needed, by moving rocks and backfilling holes with dirt and rocks. Per Right of Entry agreement with Haleakala Ranch, LLC, the Projects provided \$10,000 to the ranch for road repair activities (see Table 1).

### 2.2 Nēnē Monitoring

#### 2.2.1 Sightings

Weekly observations and monitoring were conducted by AES personnel at the Ranch from December 8, 2022 to April 30, 2023 when weather permitted and Ranch personnel approved access. Biweekly (every 2 weeks) observation and monitoring was conducted from May 1 to June 30, 2023.

Observations of banded and unbanded birds were recorded at the Ranch to monitor movements, distribution, and survival of nēnē using both visual, binocular surveys, as well as footage from three strategically placed game cameras within the pen. In FY 2023, 13 distinct banded adults and, at minimum, three unique un-banded adults were observed at the Ranch.

#### 2.2.2 Nesting

During nesting season, records were kept on mated pairs and the breeding status of females found at the Ranch. Nests found at the Ranch were marked using GPS and checked weekly to determine their status. Nesting activities, nest outcomes, hatching, and fledgling success were recorded for the

nesting season. Survey methods for nesting activity/success included both weekly visual (binocular) surveys, as well as daily data collection by on site game cameras.

Three nests or nesting attempts were located within the Ranch open-top release pen this year (Table 2). All three of these nests were successful. Six nēnē hatched, and five successfully fledged from the Ranch open-top release pen this season. AES personnel confirmed the fledging of all five goslings by compiling data from both visual observations, as well as by daily photo documentation taken by game cameras between February 16 and June 30, 2023 (Appendix A). No nests were observed outside of the nēnē pen in the 2022 – 2023 breeding season.

**Table 2. Nēnē Nesting Summary for 2022 – 2023 Breeding Season**

| Parameter   | Number      |
|---|-------------|
| <b>Nests</b>  |             |
| Located in open-top pen                               | 3           |
| Successful  | 3           |
| Abandoned   | 0           |
| Depredated  | 0           |
| Failed (other reason)                                 | 0           |
| Renests   | 0           |
| <b>Eggs</b>   |             |
| Known   | 6           |
| Destroyed naturally                                   | 0           |
| Depredated  | 0           |
| Salvaged  | 0           |
| Hatched   | 6           |
| <b>Goslings/Fledglings</b>                            |             |
| Known goslings  | 6           |
| Goslings depredated                                   | 0           |
| Goslings died (other reason)                          | 1 (Unknown) |
| Fledglings fledged from pen (credited for mitigation) | 5           |

## 2.3 Pen Maintenance

The open-top pen's fence line was continuously monitored and maintained since AES began pen management in December 2023. The fence line was weed-whacked and mowed for weed control, and trees were trimmed along the exterior boundary to prevent bridge entry by predators. The large pond was cleaned and flushed twice a month, and smaller baths were cleaned and maintained weekly. The water system's shutoff valve was replaced after it was found to be leaking. New electric fence insulators, solar batteries, and grounding stakes/wires were installed to get electric fence perimeter back up and running (AES found the electric fence was non-operational in December

2022 upon beginning operations). A large storm event on December 18, 2022, damaged many surrounding trees, the pen entrance door, and the water catchment/mower shed. Downed trees, damaged sections of fence, the pen door, and the shed were mended, with unusable damaged materials removed from the site and disposed of by AES personnel.

## 2.4 Habitat Management

Short grass habitat was maintained at the open-top release pen. During the breeding season (December 8<sup>th</sup> – May 1<sup>st</sup>), the 1-acre open-top pen was mowed once a week and the area around the outside of the pen was maintained as needed. During the non-breeding season (May 1<sup>st</sup> – June 30<sup>th</sup>), the open-top pen and the surrounding perimeter was mowed every other week and non-native/overgrown vegetation was cleared around potential nesting areas as needed. A total of 25.5 acres<sup>1</sup> was mowed this year to maintain nēnē short grass habitat. Approximately 0.5 acres of alien vegetation was mechanically removed, including lantana (*Lantana camara*), strawberry guava (*Psidium cattleianum*), Bocconia (*Bocconia frutescens*), fireweed (*Senecio madagascariensis*), and bur from both open top pens and covered secondary enclosures.

## 2.5 Predator Control

Predator traps are used to control rats (*Rattus rattus*), mongoose (*Herpestes javanicus*), and feral cats (*Felis catus*) that may pose a threat to nēnē and their nesting sites. Traplines were baited and checked weekly at the Ranch during the breeding season, and biweekly during non-breeding season using 16 Tomahawk live traps, 10 DOC 200 traps, and five A24s.

This year at the Ranch, nine mongoose and three rats were removed through predator trapping. Five of the nine mongoose were trapped by Doc 200s inside of the nēnē pen, and two of the five were caught while nēnē were actively sitting on nests between the months of December and February (Table 3). No avian predators were controlled this season at the Ranch.

Multiple observations were made of two pueo, (Hawaiian short-eared owl, *Asio flammeus sandwichensis*) pairs hunting above and around the nēnē pen during nesting season. The first observations of pueo near the pen were made on March 18, 2023. Additionally, a single gosling from pair AL/- -, ACJ/AL was confirmed missing on March 10. No gosling carcass or remains of any kind were recovered after extensive searching, indicating cause of predation may be avian. There is currently no formal program in place for the removal of avian predators.

---

<sup>1</sup> One acre inside pen mowed 23 times plus 0.25 acres of pen exterior mowed 10 times.

**Table 3. Traps Deployed and Predators Removed during 2022 – 2023**

| Location  | Trap Type  | Trap nights      | Mongoose | Cat | Rat |
|---|------------|------------------|----------|-----|-----|
| Outside pen   | DOC200 (5) | 204              | 1        | 0   | 1   |
|   | Cage (16)  | 154 <sup>1</sup> | 4        | 0   | 0   |
| Inside pen  | DOC200 (5) | 204              | 5        | 0   | 0   |
|   | A24 (5)    | 204              | 0        | 0   | 0   |
| 1. Live traps were closed and moved inside after all goslings were confirmed fledged. Traps were moved to avoid damage by cattle moved to the area for grazing. |            |                  |          |     |     |

## 2.6 Relocations

According to records provided by DOFAW (pers. comm. Colton Loque via email on 3/21, 4/26, and 6/22/2023), three nēnē were relocated to the open-top release pen by DOFAW personnel in FY 2023. All were injured birds that were captured, treated, and relocated to the pen. On March 21, 2023, a bird with a broken wing from the Big Island was released inside of the pen (AL 798-24941/\$3T8)<sup>2</sup>. On April 18, 2023 a bird missing its right foot (#1158-78271/--) was released inside of pen, and on June 22, 2023 a bird with an injured left wing (\*ECN/AL #1158-78275)<sup>3</sup> was released inside of pen. None of the released birds bred at the pen this year, and none of the released birds were regularly documented visitors of the pen after the initial release date.

## 2.7 Injury, Fatalities, Disease

The only nēnē deaths that occurred this season at the Ranch was of a single gosling due to unknown causes.

## 2.8 Adaptive Management Actions

High amounts of rainfall during the breeding season led to the access road becoming impassable for numerous weeks on end, making regular visitations challenging at times. An apparent lapse in vegetation management between the end FY 2022 and the Projects' assuming management activities through AES resulted in grass lengths becoming too tall for a standard lawn mower to handle. Extensive grass management via weed-whacker has been required throughout the FY to get most short grass habitat back to manageable levels. Based on the length of the grass upon taking on management activities, the on-site riding mower was not able to be used due to lack of mower deck clearance. Grass management has included an estimated additional 64 hours between December 8, 2022 and June 30, 2023 to reduce grass length throughout the pen and around the perimeter (Appendix A [see images 11 – 14]).

<sup>2</sup> \$ denotes birds banded from 1994- present.

<sup>3</sup> \* denotes birds banded from 1990-1994.

## **2.9 Nēnē Produced (Mitigation Credit)**

Five nēnē were produced and successfully fledged at the pen during the 2022 – 2023 breeding season. These fledglings, and the opportunity for increased adult survival for the 13 banded and three unbanded occupants of the pen will contribute to mitigation credits for the Projects. Mitigation credits accrued with the 2022 – 2023 breeding year will be equally divided between KWP I and KWP II per the MOU.

**Appendix 7. Makamaka'ole Seabird Mitigation Area 2022  
Breeding Season Annual Report**

# **Makamaka‘ole Threatened and Endangered Seabird Mitigation Project: Exclosures and Artificial Burrows Annual Summary Report**

---

**Reporting Period:** January 1, 2022 – December 16, 2022

*Monitored and Reported by Maui Nui Seabird Recovery Project for Brookfield Renewables and Tetra Tech*

---

**Overall Summary:** The Makamaka‘ole seabird mitigation site consists of 2 predator-proof exclosures, each housing 50 artificial seabird burrows with nest boxes. Since 2016, social attraction mechanisms including seabird models and nighttime auditory playback have been in place to attract Newell’s shearwaters (*Puffinus newelli*, NESH) in exclosure A, and Hawaiian petrels (*Pterodroma sandwichensis*, HAPE) in exclosure B (the NESH auditory playback has been inactive since 2020 due to regularly attending NESH adults). MNSRP began monitoring Makamaka‘ole in May 2020 and continued standardized methodology through the 2021 and 2022 breeding seasons. This year we report a total of 18 NESH eggs produced at 14 burrows, 1 of which hatched a successfully fledged chick (Figure 1). This is an increase of 2 total NESH eggs at three additional burrows since 2021, although the fledged chick count remains the same as last year. Twenty-eight burrows were consistently active, an increase of three over 25 in 2021. Bulwer’s petrels (*Bulweria bulwerii*, BUPE) were present in two burrows in exclosure B. No HAPE were detected inside the exclosures.

Genetic analysis of blood and feather samples from 14 adult NESH in nest boxes collected in August and September revealed sampled birds are female. Females may attend new colonies before males or be more likely to occupy artificial burrows in August and September. Additional sampling is needed to understand the sex ratio of colonizing birds at Makamaka‘ole.

Trapping and baits deployed in bait stations to remove predators is consistent and ongoing. Mongooses were captured only outside the exclosures, but rats and mice were removed from inside and outside the exclosures. Poison bait consumption remained relatively low throughout the year, peaking in the winter months.

Maintenance and refurbishment of the exclosure fences and other infrastructure continues as time and resources allow.

## **Vegetation Control:**

Vegetation is cleared and regularly maintained throughout the season around the inside and outside of the exclosure fences, around burrow boxes and burrow entrances, around traps and bait stations, and along interior pathways and between exclosures. Hand-pulling is used around burrow entrances and game cameras, and weed whackers are used along fences and trails. Keeping these areas clear is critical for allowing fence inspection, burrow entrance and egress by the birds, and staff access to critical areas during monitoring activities. Because of the rapid rate of growth of the dominant grass species, hand trimming and pulling occurs around the burrows during every visit, and weed-whacking occurs 2-3 times per month. Weed cloth was installed under some game cameras to keep grasses from interfering with motion detection action.

**Figure 1.** NESH chick being weighed by Kupu ‘Āina Corps member Joshua DeCambra on 9/27/22.

#### **Exclosure Fence – Status and Activities:**

Fence and infrastructure activities focused on prepping the existing structure for installation of the new mesh. New posts were installed, new belly bands were installed, erosion control structures were put in place, and dirt was moved to reestablish foundations. Further fence work including use of the new mesh will proceed during the winter months, outside of the normal seabird breeding season.

#### **Sound Playback System – Status and Activities:**

The sound playback system for HAPE in exclosure B was started on April 21. The NESH playback system in exclosure A was tested and found operational but remained off.

#### **Artificial Burrow Checks:**

All burrow boxes were opened to check activity status at the start of the season on 3/2/2022. Pictures were captured and contents and box integrity were noted. One BUPE was found in burrow 50B at that time. Two boxes were rebuilt and 6 lids were replaced. A BUPE egg was discovered in 50B in April cracked and non-viable.

Seabird activity is assessed at each burrow every other week during the breeding season by checking for removal or displacement of toothpicks erected at the entrance, searching for guano and feathers, and by noting bird scent. Motion-activated game cameras are deployed at all burrows suspected as active. NESH first appeared on game camera on 3/30/22 at 48A. NESH activity for the 2022 season was first noted during monitoring on 4/5/22. Bird sign and game

camera activity continued consistently throughout the season until the single NESH chick fledged from 25A on 10/12/22. A total of 22 burrows in A (including one natural burrow – 51A) and 6 burrows in B were considered consistently active in 2022. A burrow is considered consistently active if it produced a chick or an egg, or if NESH appeared entering on camera, or if there was more than one type of bird activity evidence during more than one burrow check, or if evidence inside the burrow box (e.g. NESH feathers, nest cups, guano) at the end of the season suggested activity when compared to the start of the season. See Table 1 for results from active burrows. All nest boxes were opened on 9/28 or 9/29/22 to check for bird activity, and to assess the condition of the boxes (see Table 2). No new natural sites were discovered this season.

On 5/10/22 the next boxes were opened to check reproductive status. Two NESH eggs were discovered in 48A. By the end of the season, a total of 18 NESH eggs were produced (16 in Exclosure A and 2 in Exclosure B), one of which produced a viable chick. Two boxes in Exclosure A each produced 2 eggs, and one box produced 3. Compared to 2021, most of the eggs did not appear cracked or damaged (likely due to the addition of the sand), yet were still nonviable. On 8/11, 8/19, and 9/09 all active burrows were opened to band adult NESH and collect samples for genetic analysis, which were sent to Kenneth Hayes, the director of the Pacific Center for Molecular Biodiversity at the Bishop Museum in Honolulu. Two out of the 14 adult were recaptures (banded in 2020). Results indicate that sampled individuals are female. This sampling and analysis was funded by the Native Ecosystems Protection & Management (NEPM) program of the Maui branch Division of Forestry & Wildlife. Adults from burrow 25A, which produced the chick were not sampled. To date, 22 individual adults and 2 chicks have been banded, all from Exclosure A.

Table 1. 2022 summary of visitation and production of active burrow boxes.

| Burrow/<br>Exclosure | 4/5/22            | 4/21/22                    | 5/10/22           | 6/6/22                                   | 6/22/22                        | 7/5/22                                   | 7/20/22                                 | 8/4/22                                   | 8/19/22                                  | 9/9/22                         | 9/28/22                                  | camera<br>activity             | box<br>activity   | Consistent<br>active |

### Nighttime Seabird Surveys:

No nighttime auditory and visual surveys were conducted during the 2022 breeding season. These surveys were not included in the 2022 scope of work for the Makamaka‘ole Seabird Enclosures monitoring.

**Predator Removal:** DOC200 traps (10 inside and 22 outside) and snap traps (20 inside and 20 outside) are deployed at the exclosures. Baits typically used are eggs for DOC200s and peanut butter for snap traps. Have-a-heart live traps are left intermittently outside exclosure A and on the path between exclosure A and B. Three mongooses were captured this year in live traps. Total catches this year to date are; 36 mongooses outside, 28 rats outside, 26 rats inside, 5 mice outside, and 11 mice inside. The overall catch rate in kill traps for the year was 0.005 (catches/trap night). Catch rate was higher at exclosure B compared to A (0.006 vs. 0.004) and higher outside of the exclosures compared to inside (0.005 vs. 0.004). See Table 3 for a summary of trapping.

Table 3. Summary of trap nights and catches, inside and outside exclosures by trap type (Jan. 1 – Dec.14, 2022).

| Exclosure | Placement | Trap Type | Trap Nights | Mongoose catch | Rat catch | Mouse catch |
|-----------|-----------|-----------|-------------|----------------|-----------|-------------|
| A         | Outside   | DOC200    | 3579        | <b>16</b>      | <b>12</b> | <b>2</b>    |
|           |           | Snap Trap | 3307        | 0              | <b>4</b>  | <b>3</b>    |
|           | Inside    | DOC200    | 1715        | 0              | <b>1</b>  | 0           |
|           |           | Snap Trap | 3085        | 0              | <b>7</b>  | <b>1</b>    |
| B         | Outside   | DOC200    | 3292        | <b>16</b>      | <b>10</b> | 0           |
|           |           | Snap Trap | 2571        | <b>1</b>       | <b>2</b>  | 0           |
|           | Inside    | DOC200    | 1343        | 0              | <b>7</b>  | 0           |
|           |           | Snap Trap | 3035        | 0              | <b>11</b> | <b>10</b>   |

Poison bait stations targeting rodents are deployed throughout both exclosures (24 in A, 22 in B). They are checked monthly and re-baited as needed with Ramik poison bait bars. The average amount of bait consumed in both exclosures is low throughout the summer (Figure 2).

Figure 2. Average amount of poison bait consumed in each exclosure (2022).

**Predator Tracking:** Tracking cards baited with peanut butter were used to assess rodent and mongoose activity within the exclosures (10 each in A and B). Tracking cards are deployed for 24 hours and checked for rodent activity, then checked again after 72 hours for mongooses. In 2021, predator tracking cards were deployed in January, April, August, and November. No mongooses were detected on tracking cards. Rat tracks were seen more frequently in Exclosure B than in Exclosure A. Rodent presence decreases throughout the summer, as suggested by bait consumption (see Table 4).

Table 4. Predator tracking results by month. Results of mouse detection as the percent of cards with mouse tracks. Rat results list specific rat detection locations.

| Month     | Percent cards with mice |     | Percent cards with rats |     |
|-----------|-------------------------|-----|-------------------------|-----|
|           | A                       | B   | A                       | B   |
| March     | 60%                     | 10% | 0%                      | 10% |

## Objective

The goal of this mitigation work was to improve reproductive success of Hawaiian petrels (*Pterodroma sandwichensis*) in a high-priority colony area on Lānaʻi, where maintenance of previous mitigation work is at risk. Support from this mitigation effort provided nesting petrels protection from predator pressure and resulted in reproductive success well above baseline levels within the project area.

## Project Background

In 2018, Brookfield Renewable Partners provided support to Pūlama Lānaʻi to partially meet the regulatory requirements of Kaheawa Wind Power's Habitat Conservation Plan (HCP). With that mitigation project, predator control and monitoring were extended to protect the endangered Hawaiian petrel colony beyond the scope of the work the Pūlama Lānaʻi Conservation Department was conducting at the time.

In 2019, Pūlama Lānaʻi was able to maintain the predator control and monitoring with internal funding. In 2020, the COVID-19 pandemic caused the Pūlama Lānaʻi Conservation Department to constrict and focus on triage of priority activities. Some cat control was continued, and rodent traps were rebaited in January 2021, but the Conservation Department struggled to complete the work with fewer staff, and the department's other endangered species efforts were completely sidelined during that time.

For 2021 and 2022, mitigation funding support from Brookfield Renewable Partners supported efforts on Lānaʻi to maintain the 2018 level of predator control and Hawaiian petrel monitoring that was at risk due to post-COVID impacts.

## Mitigation Actions

The mitigation project area consists of 4 distinct ridges, East Puʻu Aliʻi, Kanalo, West Hiʻi, and Hiʻi Center Ridge, totaling approximately 150 acres (~60 ha). The density of birds in this area is also extremely high, and at least 224 burrows have since been found across these ridges (Figure 1), out of 650 burrows known across Lānaʻi Hale.

Figure 1. Map of area supported by Brookfield Renewable Partners mitigation funding for 2022, relative to the known Hawaiian petrel burrows on Lānaʻi Hale. The area is approximately 150 acres, and encompasses nearly 35% of the known Hawaiian petrel burrows on Lānaʻi.

## Predator Control

Predator control for cats (*Felis catus*) and rats (*Rattus spp.*) was expanded within and around this area in 2018 as part of the mitigation for Kaheawa Wind Power I (Brookfield Renewable Partners). Today, those cat trap locations remain above these ridges on the Munro Trail and below on the lower Kapano and Kōʻele trap lines, which lie behind Lānaʻi City (Figure 2). During 2022, we captured 9 cats within ½ mile of the mitigation area.

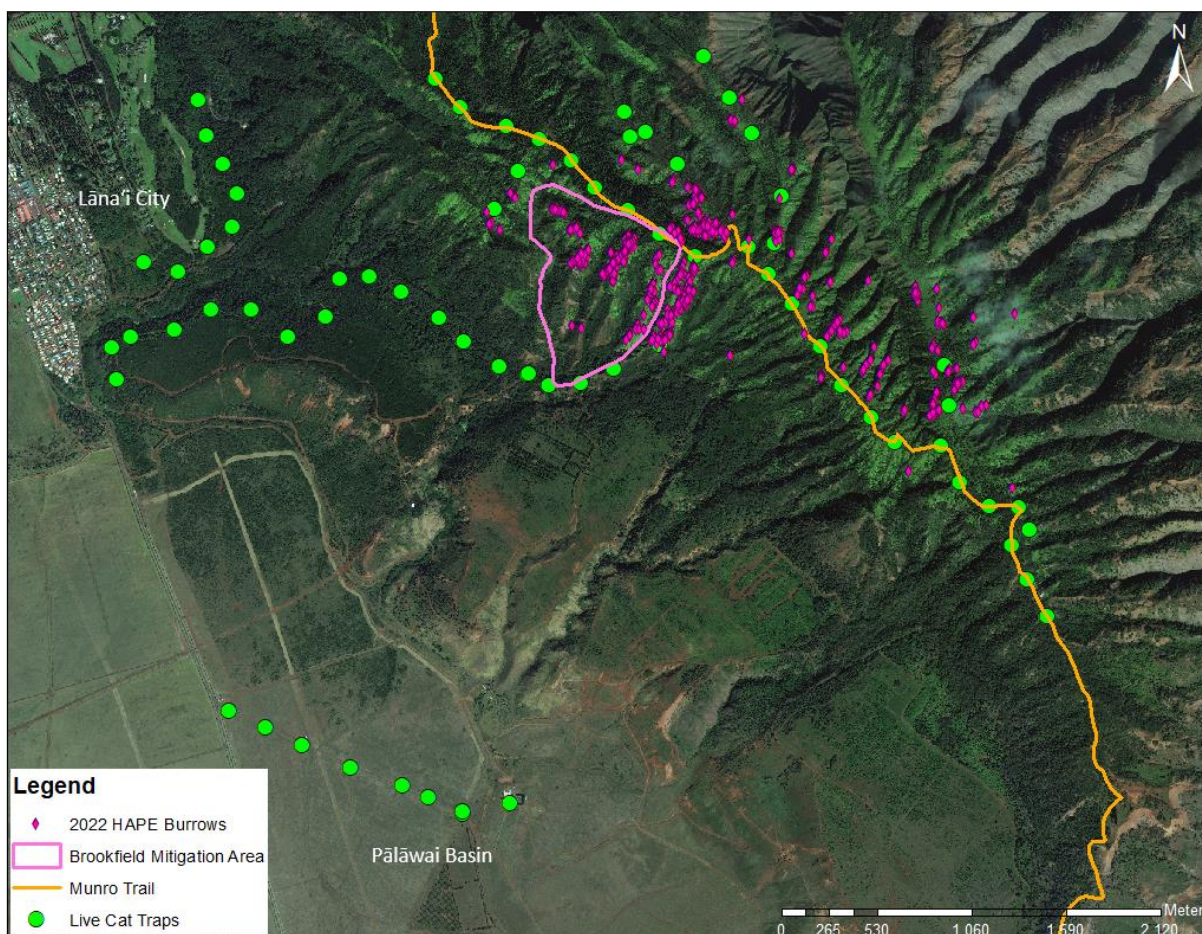

Figure 2. Locations of the landscape-level cat trap stations in the grid protecting the Hawaiian petrel colony on Lānaʻi Hale.

Throughout the 2022 season, 190 self-resetting rat traps (A24s) were active across the 150-acre native habitat area encompassing the burrows. These rat trap lines run down the ridges and through challenging canyon drainages (Figure 3). Mitigation funding provided by Brookfield supported rebaiting and maintenance of the A24 traps in the Greater Hiʻi area – this area is fully 25% of the nearly 800-trap A24 grid on Lānaʻi Hale and is the most technical terrain to traverse.

The Pūlama Lānaʻi Conservation team checked and rebaited the A24 automatic traps twice during the 2022 seabird breeding season, utilizing long-lasting automatic lure pumps (ALPs). During this time, we removed a minimum of 208 rodents, which is understood to be an extreme *underestimate*. This estimation is derived from incidental counts of skulls or carcasses found in the immediate vicinity of the A24 traps at the time of rebaiting. We also captured another 20 rats in live cat traps or other types of traps set up near cat trapping stations.

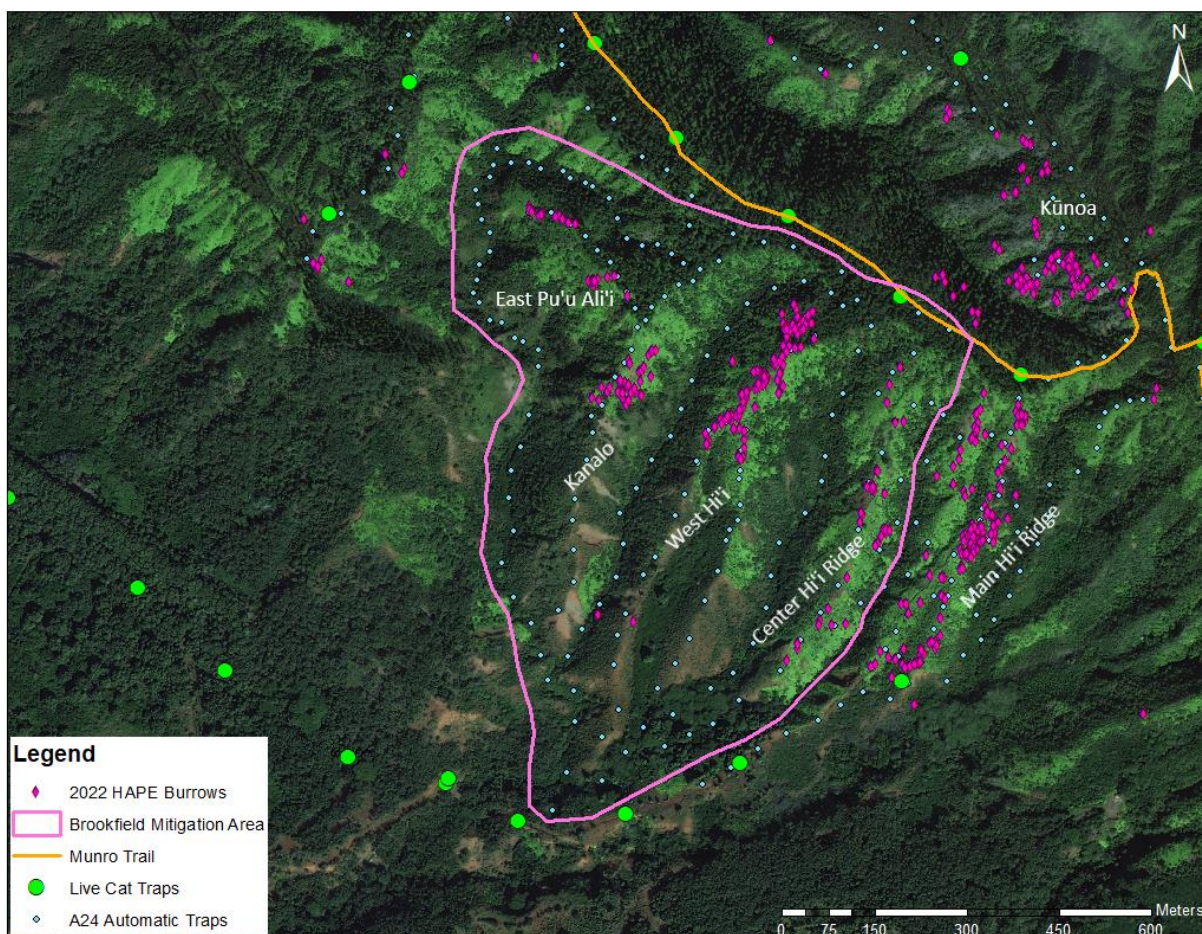

Figure 3. Locations of A24 self-resetting rat traps in the area supported by Brookfield Renewable Partners mitigation funding.

### Monitoring/Evaluation

We used 64 motion-activated cameras to monitor a subset of burrows within the project area. Burrows were selected from 2 panels, a set that remains relatively constant over time (static) and a set that changes every year (rotating). All selected burrows were consistently camera monitored, from before the start of the season until after fledging or failure. This sample of monitored burrows was then used to determine apparent reproductive success and relative proportions of inactive burrows, new prospecting pairs, non-breeding pairs, etc. for all known Hawaiian petrel burrows in the monitoring area (Table 1). Any new burrows found were added to the pool of burrows to be randomly selected from for monitoring the following year.

Table 1. Number of known burrows and monitoring outcomes in the Greater Hi'i area from 2017 to 2022.

|   | 2017         | 2018         | 2019         | 2020         | 2021         | 2022         |
|---|--------------|--------------|--------------|--------------|--------------|--------------|
| Known Burrows   | 59           | 124          | 189          | 193          | 196          | 224          |
| Monitored Burrows   | 59           | 121          | 176          | 50           | 64           | 64           |

| <i>unknown outcome</i>  | 14           | 4            | 10           | 0            | 0            | 0            |
| <i>fledged</i>  | 13           | 59           | 110          | 32           | 44           | 41           |
| <i>failed</i>   | 9            | 24           | 18           | 7            | 11           | 8            |
| <b>Chicks produced per pair (w/known outcome)</b>                   | <b>0.591</b> | <b>0.711</b> | <b>0.859</b> | <b>0.821</b> | <b>0.800</b> | <b>0.837</b> |
| Proportion of monitored burrows with known status and outcome       | 0.525        | 0.826        | 0.813        | 0.920        | 0.922        | 1.000        |
| Proportion of monitored burrows with breeding and outcome confirmed | 0.373        | 0.686        | 0.727        | 0.780        | 0.859        | 0.766        |

\*Note that from 2017-2019, cameras were moved around between burrows during the season, and burrows with likely breeding or activity were prioritized, so they were not unbiased, random samples.

## Baseline Reproductive Success

The baseline success rate without predator control on Lāna'i was calculated at 38.2% in communication with USFWS and Hawai'i DOFAW. In short, we averaged the 2016 and 2017 reproductive success estimates in colony areas with limited or no predator control.

## Impact of Mitigation Project

### Burrow Monitoring – Reproductive Success

As of December 31, 2022, there were 224 known burrows on the 4 ridges in the Greater Hi'i area (East Pu'u Ali'i, Kanalo, West Hi'i and Hi'i Center Ridge), and 64 burrows were monitored on those ridges as part of our 2022 monitoring plan (Figure 1). We confidently determined the breeding status and outcome of 100% of the monitored burrows, and 76.6% of the monitored burrows had confirmed breeding attempts (Table 1).

Of the burrows with breeding attempts, 83.7% successfully fledged a chick (n = 49). Causes of nest failure included 6 abandoned eggs, and 2 failures at the egg stage for unknown cause (no depredation detected). Review of photos from the 64 burrow monitoring cameras (~1.7 million photos) did not detect any feral cat visits to burrows.

### Net Fledgling Outcomes

Our monitoring program uses a standardized random selection of Hawaiian petrel burrows to monitor, allowing for application of the proportions of inactive, prospecting, breeding, status burrows and reproductive success rates to be applied to all known burrows in a given area. Calculation of the net benefit uses the monitored set of burrows in 2022 to determine: 1) the proportion of burrows that have confirmed breeding (i.e., estimated active nests), and 2) the apparent reproductive success rate for burrows in the Greater Hi'i area. The estimated number of fledglings produced from the known burrows minus the calculated baseline determines the net fledglings produced as a result of the mitigation actions:

$$\begin{aligned}
 & (\# \text{ known burrows} * \text{proportion with confirmed breeding} * 2022 \text{ success rate}) \\
 - & \quad (\# \text{ known burrows} * \text{proportion with confirmed breeding} * \text{baseline success rate}) \\
 = & \quad \text{net fledglings produced}
 \end{aligned}$$

In 2022, the calculated benefit of predator control in the Greater Hi'i area was 78 Hawaiian petrel chicks above baseline, given the currently known number of burrows (Table 2).

Table 2. Calculated increase in 2022 Hawaiian petrel fledgling production in response to predator control in the proposed mitigation area.

|  | 2022  |
|--|-------|
| # Known Burrows  | 224   |
| Estimated number of burrows w/breeding attempts <i>(based on 0.77 proportion of burrows monitored with breeding attempts; Table 1)</i> | 172   |
| Apparent Reproductive Success Rate   | 0.837 |
| Benefit of predator control above 0.382 baseline (net fledglings produced)   | 78    |

## Conclusion

Support from this mitigation effort provided nesting petrels protection from predator pressure and resulted in reproductive success well above baseline levels within the project area.
